OUR TC_RATE ASSUMPTION

What this measures

Every market centre must publish, monthly, the execution quality it delivered — broken out **per ticker, per order type, and per order size bucket**. This report uses the two venues that together handle the largest share of E*TRADE order flow (Citadel ~25–29%, HRT ~16–20%).

Effective spread — the cost actually paid, not the posted quote. $S = 2 \times |P - M| / M$ where P = trade price, M = quote midpoint

Worked example: stock quoted 49.98 bid / 50.02 ask, so M = 50.00. You buy at P = 50.01 (inside the quote — price improvement). Then $S = 2 \times |50.01 - 50.00| / 50.00 = 0.0004 = 4 \text{ bps}$. Had you paid the full ask of 50.02, $S = 2 \times 0.02 / 50 = 8 \text{ bps}$ — the full quoted width.

Why effective spread ≈ round-trip cost. One-way cost is $|P - M| / M$, i.e. *half* the effective spread. A round trip (buy then sell) pays that twice — so it equals S itself. That makes these numbers **directly comparable to our TC_RATE = 0.0005 = 5 bps per side = 10 bps round-trip**.

bps (basis points) — 1 bp = 0.01%. So 10 bps = 0.10% = \$1,000 on a \$1,000,000 trade.

Order size buckets — Rule 605's four share-count categories: 21 = 100–499 sh 22 = 500–1,999 23 = 2,000–4,999 24 = 5,000–9,999

Bucket 24 is the largest that exists: the rule defines "covered orders" as those **under 10,000 shares**, so nothing bigger is ever reported.

Slope (our shorthand in this report) — the ratio $\text{bucket 24 cost} \div \text{bucket 21 cost}$, i.e. how many times more expensive the largest observable order is versus the smallest.

Worked example: STRL costs 6.75 bps at 100–499 sh and 47.74 bps at 5,000–9,999 sh on Citadel → slope = $47.74 / 6.75 = 7.1\times$.

Method

- **Order types:** market (code 11) and marketable-limit (12) only — the liquidity-*demanding* orders. Non-marketable limit orders (13/14/15) provide liquidity and their spread means something different.
- **Share-weighted:** each monthly cell weighted by shares executed, so a month with heavy volume counts proportionally more than a thin one.
- **Prices:** dollar spreads converted to bps using the **historical monthly average close** for each ticker over the matching month (from `daily_equity_prices`), not today's price — so a name that moved 40% over the year is converted correctly month by month.
- **Sample filter:** a (ticker, bucket) cell needs ≥20,000 shares over the 12 months to be included, dropping thin-sample noise. 404 of 444 names survive with data at both the smallest and largest bucket on both venues.

Headline finding

Cost rises **steeply and monotonically** with order size — roughly **4.1×** from the smallest to the largest observable bucket. At the largest bucket the median name costs **8.88 bps**, essentially *at* our 10 bps assumption, and **181 of 404 names (45%)** exceed it.

This refines the earlier conclusion, it doesn't contradict it. The prior figure (~1.7 bps median, "TC_RATE is conservative") was share-weighted across *all* order sizes and was therefore dominated by small retail orders, which genuinely are that cheap. Once you condition on size, the gradient appears. Both numbers are correct — they answer different questions.

Strategy	Names >10bps @ 5–10k sh	Share
LV	12 / 68	18%
MR	130 / 281	46%
MOM	64 / 123	52%

LV's large, liquid names hold up well. MR and MOM — which reach into mid-caps and higher-volatility names — are roughly half above the assumption at this size.

Median effective spread by order-size bucket

Both venues agree closely on the shape: cost roughly quadruples from the smallest to the largest observable order. The dashed line is our 10 bps round-trip assumption.

Bucket	Shares	Citadel	HRT
21	100–499	2.57 bps	2.6 bps
22	500–1,999	3.54 bps	3.55 bps
23	2,000–4,999	6.94 bps	6.83 bps
24	5,000–9,999	9.91 bps	8.66 bps

Slope vs. absolute level — which names actually matter

A steep slope alone is **not** a danger signal. The steepest slopes in the whole sample belong to mega-caps that start almost free: NVDA runs 0.14 → 0.93 bps (6.6×), VRT 0.48 → 11.9 bps (24.8×). Multiplying a near-zero base by 20 still leaves a small number.

What matters is the **upper-right region**: names that are already expensive at small size *and* climbing. Hover any point for the name.

Horizontal dashed line = 10 bps assumption. Points above it already exceed our cost assumption at under ~\$1M of notional.

Names exceeding 10 bps at 5,000–9,999 shares

Sorted worst-first by the two-venue average. Click any column header to re-sort. **b21** = cost at 100–499 sh; **b24** = cost at 5,000–9,999 sh; both in bps.

ADV CAP PER NAME PER DAY

What this simulates

MR trades daily and reaches into mid-caps — so at size it cannot always establish or exit a position as fast as the strategy wants. This models that directly: MR carries an **aspirational** portfolio (the locked C150/X10 equal-weight 10 names) and a **real** portfolio that may trade at most **10% of each name's ADV per day**, legging in and out over multiple days.

ADV (average daily dollar volume) — how much of a stock trades in a typical day, in dollars. Here the trailing-10-day mean of `close × volume`, validated to match the strategy's own ADV column exactly (median ratio 1.000).

The rebalancing rule (per spec). Each day the real book moves toward equal weight, each name's move capped at 10% × ADV. Capital a constrained name cannot absorb is **water-filled across the other target names first** (overweighting them above 10% up to their ADV ceilings); only when *all* target names are capped does the remainder go to **SPY**. The book starts fully in SPY and sells it down first as MR names absorb capital.

Water-fill — pour leftover budget into whichever target names still have ADV headroom, evenly, until the budget is used or every name hits its daily ceiling. It is why the book tilts toward its liquid names rather than concentrating in any single one.

Method & validation

- **Returns:** daily total return from split & dividend-adjusted close, 2001–2026, all 1,225 names MR ever held.
- **Same cost model both sides:** 10 bps round-trip TC on actual dollar turnover, applied identically to aspirational and constrained — the *only* difference is the ADV cap.
- **Validation gate:** aspirational reproduces documented locked MR to 0.1% (IS CAGR 29.5% vs 29.6%, MaxDD −71.9% vs −71.9%); SPY-only 2001–2021 CAGR 8.4%.
- **AUM sweep:** \$50M → \$5B, since the cap bites only relative to size.

In-sample results (2001–2021)

Column definitions in the "Drift & Curves" tab. Aspirational row = unconstrained locked MR.

AUM	CAGR	Vol	Sortino	Sharpe	MaxDD	mean maxW	p95 maxW	eff-N	MAD	bind%	SPY>5% days	SPY avg
Aspirational	29.5%	38.9%	1.15	0.86	-71.9%	10%	10%	10.0	0.0%	0%	0%	0.0%
\$50M	25.4%	37.8%	1.06	0.79	-72.7%	14%	24%	7.8	3.4%	97%	5%	0.7%
\$100M	25.1%	37.2%	1.05	0.79	-73.4%	15%	28%	6.9	4.5%	99%	12%	2.1%
\$250M	22.6%	36.6%	0.97	0.74	-77.5%	17%	32%	5.9	5.7%	100%	27%	6.0%
\$500M	20.7%	35.4%	0.92	0.71	-79.3%	17%	34%	5.2	6.5%	100%	42%	11.0%
\$1B	18.9%	33.7%	0.88	0.68	-81.0%	16%	36%	4.7	7.2%	100%	59%	20.5%
\$2B	16.4%	32.3%	0.80	0.63	-79.7%	15%	38%	4.4	7.8%	100%	71%	29.9%
\$5B	15.4%	27.3%	0.82	0.66	-72.1%	10%	36%	4.0	8.8%	100%	92%	52.8%

Performance suffers smoothly, with no cliff. Even \$50M costs ~4 CAGR points (29.5→25.4); ~7 by \$250M, ~11 by \$1B. MaxDD actually *worsens* mid-range (–72% → –81% at \$1B) before improving at \$5B — only because by then over half the book sits in SPY, no longer really running the strategy.

Capacity frontier — CAGR, MaxDD & Sortino vs. AUM

The give-up is a slope, not a wall — "max AUM" is a tolerance choice for how much CAGR and index-drift you accept. The earlier static P25-ADV estimate (~\$296M) lands right where the strategy is still recognizably itself.

Column definitions

- **CAGR** — compound annual growth rate.
- **Vol** — annualized standard deviation of daily returns.
- **Sortino** — annualized return ÷ downside deviation (only down days). Higher better.
- **Sharpe** — annualized return ÷ total volatility.
- **MaxDD** — worst peak-to-trough decline.
- **mean maxW** — day-averaged weight of the largest position (equal-weight baseline = 10%).
- **p95 maxW** — 95th-percentile largest-position weight; the tail of concentration.
- **eff-N** — effective holdings = $1 \div \sum(\text{weight}^2)$ (inverse Herfindahl). 10 = perfectly equal-weighted; lower = concentrated.
- **MAD** — mean absolute deviation of weights from 10%; 0% = perfectly equal.
- **bind%** — % of days ≥ 1 target name cannot reach 10%. Saturates near 100% even at small AUM because MR churns daily (almost always a fresh name mid-leg-in).
- **SPY>5% / SPY avg** — % of days SPY overflow exceeds 5%, and average SPY weight. The meaningful capacity signal: negligible below ~\$250M, then climbing.

Concentration & index drift vs. AUM (in-sample)

As AUM rises the water-fill pushes capital into the few liquid names (eff-N falls 10→4), then spills to SPY (right axis) once even they are capped. Beyond ~\$1B the MR sleeve *de*-concentrates only because overflow goes to the index.

Equity curves (rebased to 100), 2001–2026

Aspirational vs. each AUM; the fan widening after ~2010 is capacity drag compounding. Log scale.

SPY overflow over time

Share of the book parked in SPY because the ADV cap blocked deployment into MR names. Near zero at \$50–100M; a structural third of the book at \$1B+.

The ceiling — why every number here is a floor

Rule 605 "covered orders" **exclude anything at or above 10,000 shares**. Bucket 24 (5,000–9,999 sh) is therefore the largest order size that exists anywhere in this dataset.

In dollar terms that ceiling is small — median ~\$895,000 of notional (P25 \$449K, P75 \$1.78M) across these names. Against our own position sizes at a 10% weight:

AUM	Position @ 10%	vs. largest observable order
\$50M	\$5.0M	6× larger
\$100M	\$10.0M	11× larger
\$300M	\$30.0M	34× larger

Critically, **the cost curve is still rising at the ceiling** — median 4.1× with no sign of flattening between buckets 23 and 24. So these figures are **lower bounds**, not estimates of what we would pay at our sizes.

Other caveats

- **Two venues, not all seven.** Citadel and HRT are the two largest destinations for E*TRADE flow but together are roughly 45–50% of it. G1, Virtu, Jane Street, Two Sigma and GTS are not included here.
- **Retail flow, not ours.** These are the executions those venues gave *all* their order flow, predominantly retail. Our order profile differs.
- **Not depth.** This is realised cost by size, not order-book depth. The only depth data we hold is a single ~5-minute top-of-book snapshot from 23 Jul 2026, which is too thin to characterise typical depth.
- **12 months, not 3 years.** The 36-month reach comes from the *ticker universe* (every name held over 3 years); the execution data itself is 12 months.
- **MR capacity model:** daily total-return panel, same 10bps TC both sides, ADV self-computed and validated against the strategy's own column -- but the water-fill/SPY-overflow mechanics are our modeling choice implementing your spec, not something independently verified against real trading.
